

PLATFORM, INFRASTRUCTURE & AGENTIC AI ENGINEERING

Amin Al Ali Al Darwish

Platform Engineer · Agentic AI Systems ·
Architecture & Delivery

I am a platform engineer. I build the paved roads other engineers ship on: internal developer platforms, reusable cloud infrastructure, and CI/CD pipelines that make the safe path the fast one. Lately that means agentic AI in production systems — coding agents working inside real codebases, MCP-based tooling, and guardrails scoped to what a change can actually reach. This page collects the work behind that, and what actually got built.

WHAT I WORK ON seven practice areas

Internal developer platforms

Self-service environments, golden paths, environment templates and standardized delivery workflows that cut the toil out of shipping.

Cloud & infrastructure

AWS, Azure, GCP and DigitalOcean, including hybrid patterns and serverless architectures — Lambda, EventBridge, DynamoDB, S3, CDK/SAM.

Kubernetes & containers

Kubernetes (CKA), Helm, Argo CD, Docker. Cluster design for production workloads and for local developer sandboxes.

Reliability & governance

SLO thinking, incident response, postmortems and runbooks; guardrails and least-privilege defaults baked into the delivery flow.

Infrastructure as code

Terraform modules built for reuse, environment standardization and policy-aligned provisioning across teams.

AI & agentic engineering

Coding agents pointed at real codebases, MCP servers and in-IDE assistants, and guardrails scoped to what a change can actually reach rather than to file paths.

CI/CD & release engineering

GitHub Actions, GitLab CI, CircleCI, GitOps and progressive delivery — release paths that stay predictable under change.

SELECTED WORK eight pieces

Forward Earth
2026

Serverless workloads in a local cluster

A Kubernetes-based sandbox for testing AWS Lambda workloads on a developer machine rather than in the cloud. A known tooling limitation blocked the obvious approach, so the cluster runs nested inside its own container runtime.

Proved with live event-bus and object-storage integration first, then scaled up to validate a full serverless microservice end to end.

Kubernetes

AWS Lambda

EventBridge

S3

Docker

Mapping a serverless architecture

Documented a serverless architecture as an event-flow map rather than a resource list: every event source traced through the components it touches, each edge recorded with the confidence behind it, and anything unresolved flagged instead of guessed.

Serverless architecture

Event-flow mapping

Architecture documentation

Guardrails shaped like the blast radius

Path-based guardrails do not hold across service boundaries. An agent told to stay inside `service-a` obeys, then relaxes a field on a response and stops emitting an event it judged redundant — `service-b`'s files are byte-identical and `service-b` is broken.

Defined the constraints in the vocabulary the damage actually travels in: contracts, events and the edges between services, rather than directories.

Blast radius

Preview environments for async pipelines

Scoped adapters that let asynchronous data-processing flows run in preview and staging environments, designed to fit existing orchestration rather than replace it.

Preview environments

Async data processing

Orchestration

Paved roads across four clouds

Terraform modules, Helm charts, Kubernetes manifests and Docker baselines pulled into one reusable delivery standard, with CI/CD running on GitHub Actions, GitLab CI, CircleCI and Argo CD.

Environment setup and manual release effort each dropped by an estimated 10–20%, and standardized runbooks made production operations across AWS, Azure, GCP and DigitalOcean repeatable rather than heroic.

SRE

AI workloads on the platform

Extended the platform to LLM application stacks with ready-made environment templates for LangChain and LlamaIndex, so those stacks could be stood up reproducibly instead of assembled by hand each time.

Added an MCP server and an in-IDE assistant, putting the platform within reach of the tools engineers already had open.

LangChain

LlamaIndex

VS Code extension

TypeScript

Dockerfiles written by reading the repo

Contributed to an agentic system that reads a repository — language, package manager, build steps, entrypoint — and writes its Dockerfile, so a service can be containerized without one being hand-authored first.

Shaped the approach and validated the generated output against real project structures rather than clean examples, which is where generated build files tend to fail.

Developer environments

600+ sites, moved in waves

Migrated more than 600 websites across providers with phased cutovers, each wave gated by a runbook and validation checkpoints. Cutover-related incidents fell an estimated 10–15%; a parallel optimization pass took an estimated 8–15% off cloud spend without trading away reliability.
